This study determined the concentration and accumulation pattern of REEs in the soft tissue of *Saccostrea cucullata* with respect to interspatial variability. Variability in the concentration of REEs in soft tissue of *S. cucullata* was observed in all samples with significant differences among samples associated with sampling sites ( $p < 0.05$ ). The distribution pattern of REEs' concentration in soft tissue of *S. cucullata* is uniformly distributed among sampling sites with enrichment of light REE, LREE over heavy REE, HREE. The same accumulation pattern indicate that REEs are transported as a coherent group in aquatic ecosystem. All REEs yielded positive correlation among each elements in the soft tissue of *S. cucullata*. Average distribution of REEs in soft tissue of *S. cucullata* indicated that East Johor has the most abundance of REEs' concentration compared to Terengganu coastal water. This occurrence probably due to higher urbanization and industrialization activities such as sewage and effluent wastes. ST10 located in East Johor region has the most abundance of REEs while ST4 located in Terengganu region has the lowest concentration of REEs with Ce as the most abundance element and Dy as the least abundance element. The distribution pattern of REEs' concentration in this study is slightly different. There is significant differences between concentration of all REEs in the soft tissue of *S. cucullata* in the year of 2013 and 2017 except for La, Ce and Nd ( $p < 0.05$ ).

## KEYWORDS

*Saccostrea cucullata*, aquatic ecosystem, higher urbanization, abundance element.

## 1. INTRODUCTION

The rare earth elements (REE) consist of seventeen chemical elements: fifteen lanthanides; lanthanum (La), cerium (Ce), praseodymium (Pr), neodymium (Nd), promethium (Pm), samarium (Sm), europium (Eu), gadolinium (Gd), terbium (Tb), dysprosium (Dy), holmium (Ho), erbium (Er), thulium (Tm), ytterbium (Yb), lutetium (Lu), scandium (Sc) and yttrium (Y). Sc and Y are considered REE because they tend to exist in the same ore deposits with the lanthanides and exhibit similar chemical properties. La, Ce, Pr, Nd, Sm, Eu are indicated as light REE due to their atomic mass lower than 153 while Gd, Tb, Dy, Ho, Er, Tm, Yb and Lu are indicated as heavy REE because of their atomic mass greater than 153 [1,2]. The name of rare earth elements itself is a misnomer due to their abundant existence in the earth's crust and not especially rare as it named. In the Earth's crust, the estimated average concentration of the rare earth elements (REEs) is 150 to 220 mg kg<sup>-1</sup> with Ce as the most abundant element in the earth's crust at 60 mg kg<sup>-1</sup> and Tm and Lu as the least abundant ones at 0.5 mg kg<sup>-1</sup> [3,4]. However, these elements tend to occur together in nature thus, make it quite difficult to separate them from one another and find them in quantities significant enough to support their current heightened demand. Their unique physical and chemical properties have rendered them indispensable in a growing number of critical technologies [5].

REEs are widely used in areas of agriculture, national defense, new energy, biological medicine, aerospace and the nuclear industry as well as in daily life [6,7]. For example; fertilizers, automotive catalysts, luminescent

materials, high-performance permanent magnets, contrast agents in biomedical imaging, antitumor medicine and nuclear radiation detector [8,9]. These elements have been characterized neither as essential elements for life nor as strongly toxic elements in the environment. Although the environmental toxicity of REEs is largely unknown, environmental contamination has already been found in some mineralized areas as well as soils that are affected by the long-term application of sludge. REEs in soil and water are released and partly enter human body through multiple exposure pathways, especially food ingestion. As nonessential elements in organisms, the effects of REE accumulation on organisms remain fragmentary and inconsistent. Furthermore, the toxicological mechanisms and related environmental risk remain unclear [10]. Although there is no report on incidents of human poisoning through food chain, potential concerns regarding effects of continuous exposure to low levels of REEs on human health have been arising. This is due to their accumulation in blood, brain, lung, lymph nodes and bone after entering human body and long-term exposure to REE may be related to health problems such as changes in brain and bone [11-13]. REEs also have been proven to being accumulated by biota and have toxic effects similar to heavy metals [14].

Therefore, monitoring on REEs distribution and behaviour through biomonitoring is essential in assessing environment response including human exposures to natural and synthetic chemicals, based on analysis of an individual organism's tissues [15]. Mussels or other bivalves species such as oyster and clams are commonly preferred for biomonitoring of aquatic metal pollution and are enclosed as the biomonitors for the

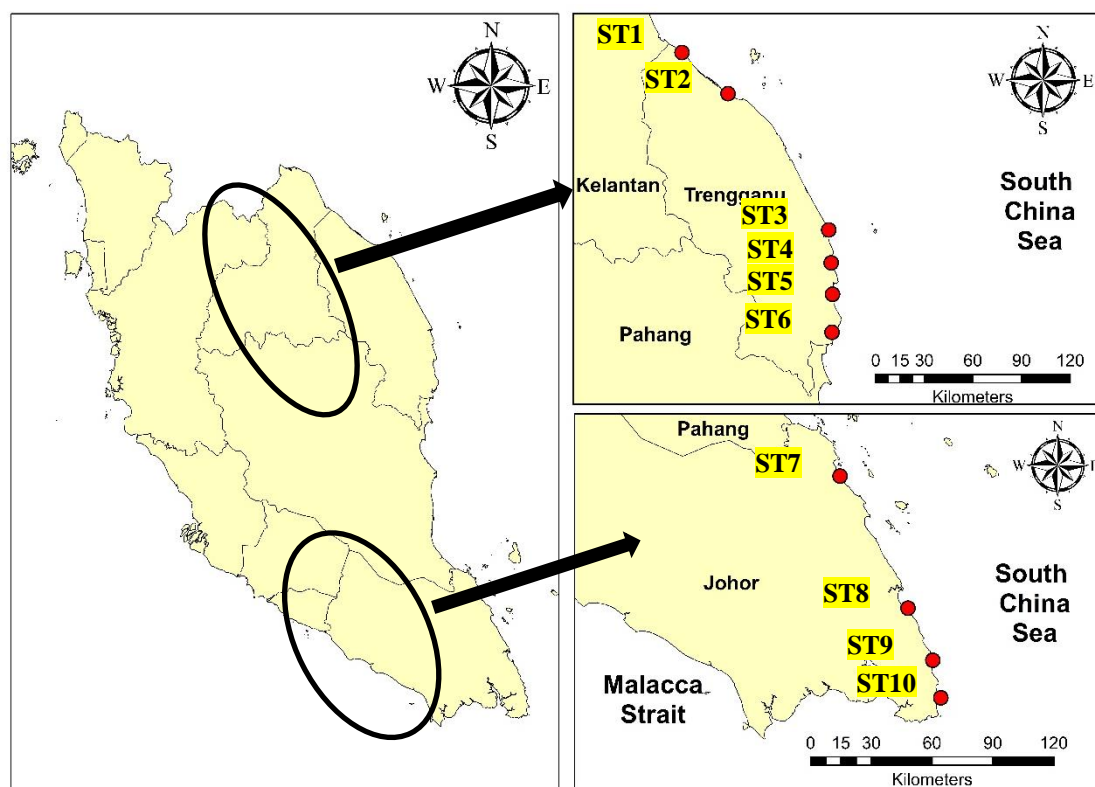

evaluation of heavy metals pollution in marine waters because of their advantages over the other organisms; wide geographical distribution, abundance, sedentary habit, tolerance to high concentrations of most environmental contaminants and their high bioconcentration factors for pollutants [16-18]. The use of bivalve and gastropods bioindicators to

study pollution in the Malaysian environment has received much attention but not on the distribution and behaviour of REEs [18-21].

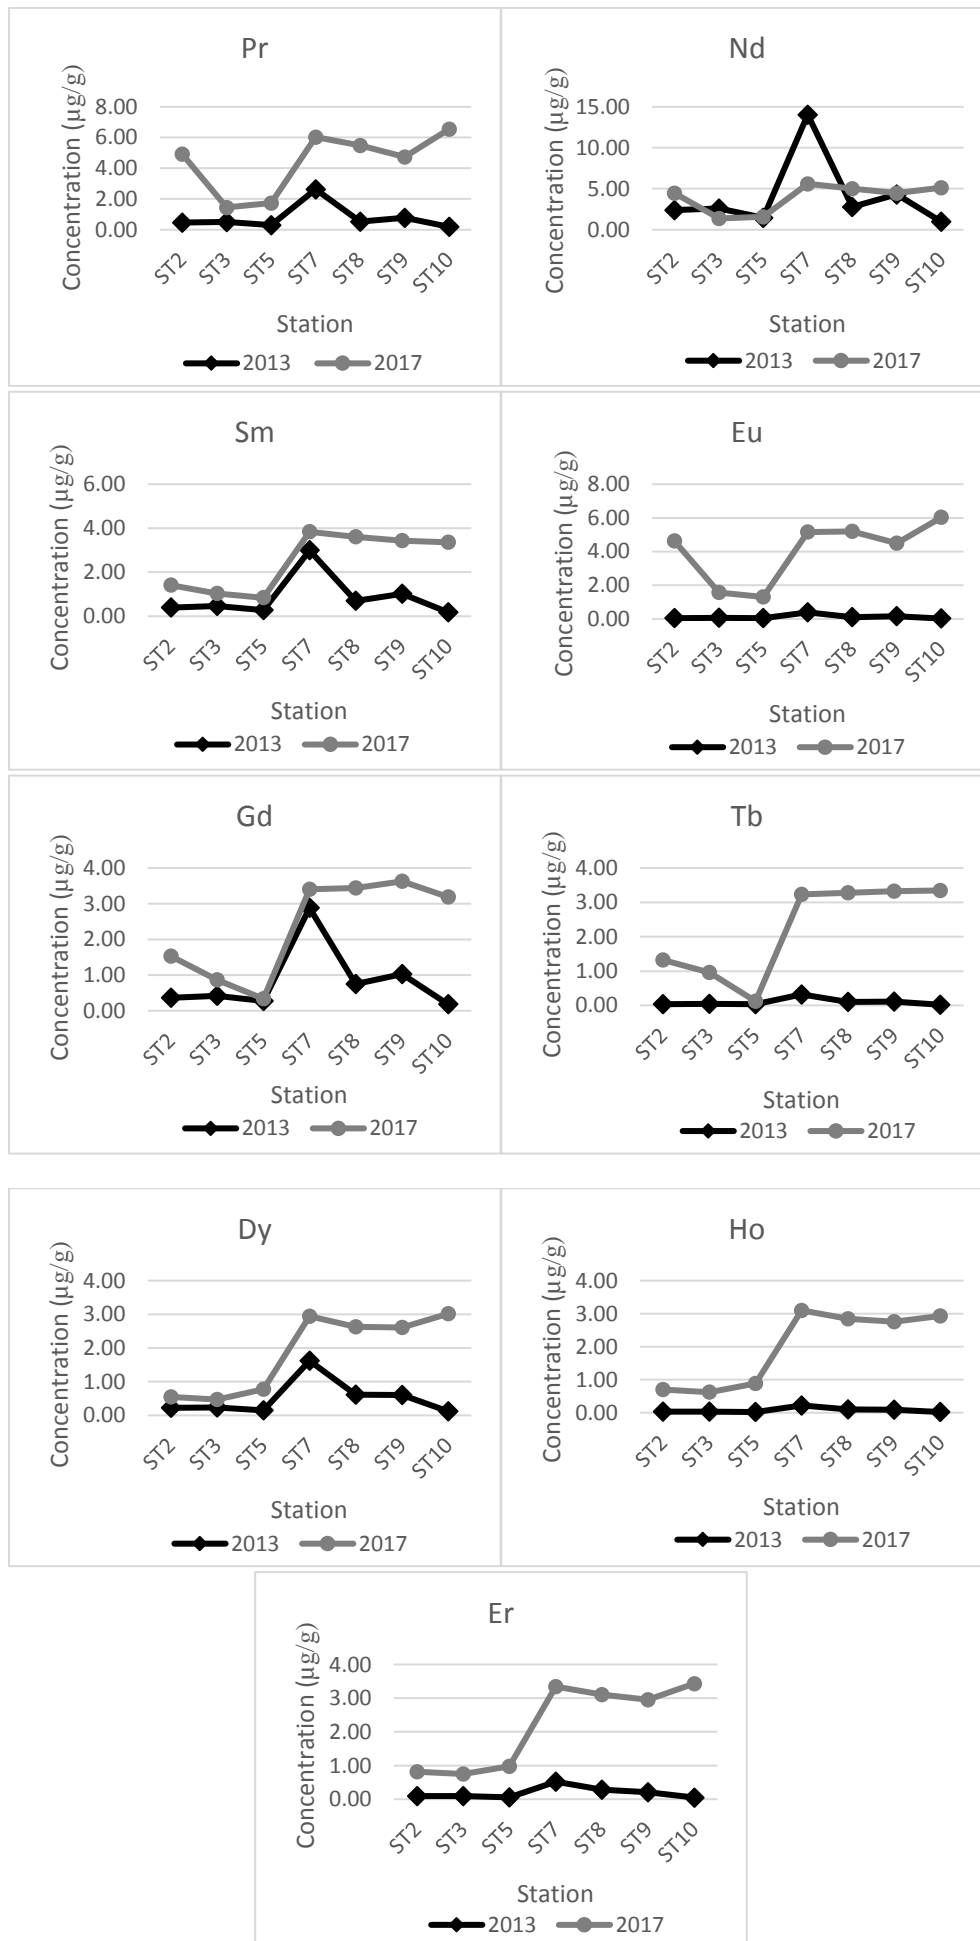

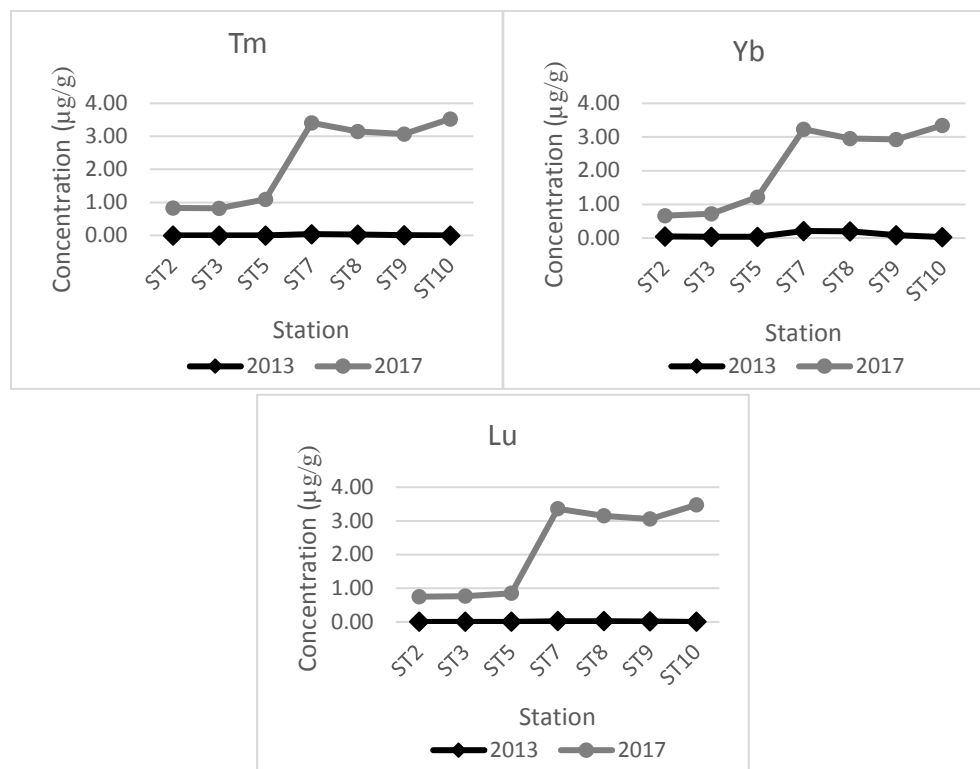

**Figure 1:** Location of sampling sites along Terengganu and East Johor coastal water.

Ten sites with abundant of *S. cucullata* population on natural rocky structures were selected and sampled along the Terengganu and East Johor coastal water. The sites chosen included pristine, recreational and proximity of industrial and urbanized areas in order to provide a wider range of information on bioaccumulation patterns in relation to environmental status. The location for each sampling site were recorded in Table 1 and Figure 1. About 30-35 individuals of *S. cucullata* with relatively similar size were hand collected during low tide. All samples were placed in plastic bags, sealed, labelled and stored on ice for transportation to the laboratory. At the laboratory, the samples were rinsed with running Milli-Q water to remove sediment and salt particles. Samples were stored frozen at  $-20^{\circ}\text{C}$  until further analysis. After thawing at room temperature, samples were extracted from their shells. In order to evaluate the water content and conversion factor, wet weight of samples were recorded. Extracted soft tissues were dried in an oven at  $60^{\circ}\text{C}$  for 3

days before being weighed again for dry weight calculation. The dried samples were pulverized to a homogenous powder using porcelain mortar and pestle. Powder sample was stored in a desiccator at room temperature until required for analysis. The analytical procedure used to measure the REEs concentration in oysters was based on with little modification [18]. Analysis REEs were carried out using an Inductive Coupled Plasma Mass Spectrometer (ICPMS) Perkin ELMER ELAN 9000. The concentration of REEs in samples was blank corrected and expressed as  $\mu\text{g g}^{-1}$  dry weight. The quality of method used was checked and confirmed in a separate comparative study of metals in a standard reference material, SRM BCR 668 Mussel Tissue. The analytical results were compiled using Microsoft Excel software and the statistical analysis were conducted by using SPSS software. SPSS was used for determining statistical data including one-way analysis of variance (ANOVA) and Pearson's correlation coefficient.

**Figure 3:** Concentration of Rare Earth Elements ( $\mu\text{g/g}$  dry weight) in soft tissue of rock oyster, *Saccostrea cucullata* from 7 sampling site along Terengganu and East Johor coastal water in the year of 2013 and 2017.

In comparison with study done, there is a significant difference between concentration of all REEs in the year of 2013 and 2017 except for La, Ce and Nd ( $p < 0.05$ ) [18]. Figure 3 shows the concentration of REEs in soft tissue of *S. cucullata* in the year of 2013 and 2017 from ST2, ST3, ST5, ST7, ST8, ST9 and ST10. The concentration of REEs in these seven sampling sites has shown increasing values of REEs' concentration except for La, Ce and Nd from 2013 to 2017. Concentration of La, Ce and Nd at ST7 in 2017 indicate a very significant decrease compared from 2013 [15]. The distribution pattern of REEs concentration in this study is slightly different [21]. This is probably due to the fluctuation of environmental parameters such as pH and temperature that affect the speciation of REEs in coastal water via their impact on the activity of  $\text{CO}_3^{2-}$  and hence impacted the amount of free REEs $^{3+}$  available for uptake by the mussels [26]. The differences of REEs' concentration in soft tissue of *S. cucullata* in the year of 2013 and 2017 in East Johor coastal water is bigger compared to Terengganu coastal water. The trend for REEs' concentration in 2013 and 2017 also shown LREEs' enrichment over HREEs in soft tissue of *S. cucullata* [27]. The enrichment of REEs' concentration in East Johor coastal water may be due to anthropogenic factors introduced by human activities resulting from urbanization and industrialization activities in the vicinity which rose rapidly by year especially in ST7.

#### 4. CONCLUSION

Concentration of REEs in soft tissue of *S. cucullata* in East Johor coastal water is more abundance compared to in soft tissue of *S. cucullata* in Terengganu coastal water. Ce has the highest average concentration among REEs while, Dy has the lowest concentration among REEs. Bioaccumulation patterns in soft tissue of rock oyster is consistent throughout the sampling sites which indicate that they are from similar origin even though their abundance are vary from each sampling sites. The distribution pattern of REEs' concentration suggested that the fractionation of REEs in coastline marine environment shows some preferential incorporation of LREE over HREE. ST10 in East Johor has the most abundance of REEs in soft tissue of *S. cucullata* while, ST4 has the lowest abundance of REEs. REEs are naturally occurrence in the environment, but massive urbanization and industrialization activities as well as anthropogenic activities contribute in the increment of REEs concentration. The distribution pattern of REEs' concentration in soft tissue of *S. cucullata* in this study is slightly different.
